

A DISTRIBUTIONAL AND CYTOLOGICAL SURVEY OF THE PRESENTLY RECOGNIZED TAXA OF *HIBISCUS* SECTION *FURCRIA* (MALVACEAE)

F. DOUGLAS WILSON¹

Summary: Wilson, F. D. 2006. A distributional and cytological survey of the presently recognized taxa of *Hibiscus* section *Furcaria* (Malvaceae). Bonplandia 15(1-2): 53-62. ISSN: 0524-0476.

Hibiscus section *Furcaria* is a natural group of plants that presently includes 109 recognized taxa. Taxa are found in subsaharan Africa, India, southeastern Asia, Malesia, Australia, islands of the Pacific basin, the Caribbean, North, Central, and South America. The basic chromosome number is $x = 18$. In nature, ploidy levels range from diploid to decaploid. The taxa exhibit a remarkable amount of genome diversity. At least 13 genomes have been identified, some distributed widely and others with more restricted distributions. No modern taxonomic monograph of *Hibiscus* section *Furcaria* exists, but a number of regional studies have appeared that are essentially global in extent. Also, a number of studies of chromosome numbers and genome relationships have been published. The present paper includes a census of all the presently accepted taxa, the geographical distribution of each taxon, and chromosome numbers and genome designations of the 49 taxa for which the information is available. Important mechanisms of speciation include genome divergence at the diploid level, followed by hybridization and allopolyploidy, significant species radiation at the tetraploid and hexaploid levels, and the development of even higher levels of allopolyploids.

Key words: *Hibiscus*, *Furcaria*, Malvaceae, taxonomy, geographical distribution, chromosomes, genomes.

Resumen: Wilson, F. D. 2006. Distribución y citología de los taxones reconocidos actualmente de *Hibiscus* sección *Furcaria* (Malvaceae). Bonplandia 15(1-2): 53-62. ISSN: 0524-0476.

Hibiscus sección *Furcaria* es un grupo natural de plantas que actualmente incluye 109 taxones reconocidos. Los taxones habitan en África al sur del Sahara, India, sudeste de Asia, Malasia, Australia, Islas del Pacífico, el Caribe, América del Norte, Central y Sudamérica. El número básico de cromosomas es $x = 18$. En la naturaleza, los niveles de ploidía varían de diploide a decaploide. Los taxones exhiben una remarcable diversidad genómica. Han sido identificados al menos 13 genomas, algunos distribuidos ampliamente y otros con distribución más restringida. No existen monografías taxonómicas modernas de *Hibiscus* sección *Furcaria*, pero se han efectuado cierto número de estudios regionales que son esencialmente de nivel global. También se han publicado estudios de números cromosómicos y relaciones genómicas. El presente artículo incluye un listado de todas los taxones aceptados actualmente, la distribución geográfica de cada taxón, números cromosómicos y la designación de los genomas de 49 taxones para los cuales existe información disponible. Los mecanismos más importantes de especiación incluyen la divergencia genómica a nivel diploide, seguida por hibridación y alloploidía, una significativa radiación de las especies a niveles tetraploide y hexaploide, y aún el desarrollo de niveles mayores de alloploides.

Palabras clave: *Hibiscus*, *Furcaria*, Malvaceae, taxonomía, distribución geográfica, cromosomas, genomas.

Hibiscus section *Furcaria* is a natural group of plants that presently includes 109 recognized taxa (Table 1). This section is set apart from the other sections of the large genus *Hibiscus* by each of the five calyx lobes having a prominent, thickened midrib and two thickened marginal ribs (Hochreutiner 1900; illustrated in Wilson 1994). Two species well known to commerce are kenaf, *H. cannabinus*, a paper-pulp and cordage fiber plant, and roselle, *H. sabdariffa*, which includes both fiber-bearing cultivars and those from which the fleshy calyces are utilized for food and drink. A number of species are grown as ornamentals or have ornamental potential with their large, showy, colorful flowers. A red-leaved cultivar of *H. acetosella* is also grown for its attractive foliage.

Hochreutiner (1900) published the last comprehensive taxonomic monograph of *Hibiscus*. No modern comprehensive monograph is available for *Hibiscus* section *Furcaria*. However, several regional publications have appeared in the last several years that in sum are essentially global in extent. Wilson

(1974), Wilson & Craven (1995), and Craven & al. (2003) published papers on the Australian taxa. Wilson (1993) treated the taxa that occur in the Pacific Basin. Wilson (1999) dealt with the African, Asian and Malesian taxa. Menzel & al. (1983a), Fuertes (1992), Fryxell & Krapovickas (2004), Krapovickas & Fryxell (2004) and Krapovickas (2006) published on the American taxa. The present paper includes a census of all presently accepted taxa and references to the original papers that include keys, typification, descriptions, synonymies, geographical distributions, chromosome data, and illustrations.

Geographical distribution: *Hibiscus* section *Furcaria* has a distribution from 35 deg. N in the southeastern United States (*H. aculeatus*) to 32 deg. S in South America (*H. diversifolius* subsp. *rivularis*), to 34 deg S in Africa (*H. diversifolius* subsp. *diversifolius*) and to 35 deg. S in Australia and New Zealand (*H. diversifolius* subsp. *diversifolius*) (Table 2).

Chromosome numbers and genome designations

The basic chromosome number is $x = 18$ in the 49 taxa that have been counted (Table 2). Margaret Y. Menzel, her colleagues and students published a series of papers that established genome relationships among most of the taxa available in her collection (Wilson 1994). In nature are found diploid and the allopolyploid series of tetraploid, hexaploid, octoploid, and decaploid taxa. This group displays a remarkable amount of genome diversity. Thirteen genomes have been identified (A, B, C, D, E, G, H, J, P, R, V, X, and Y). Subsaharan Africa is the center of genome diversity; nine of the 13 genomes (A, B, C, D, E, G, H, X and Y) and nine of the 10 confirmed diploid species are found in subsaharan Africa (all except *H. costatus* of Cuba, Central America and Mexico) (Wilson 1994).

The "G" genome (or a modified G genome) is widely distributed. Found only in one diploid species in Africa, *H. sudanensis*, it is also found in an African tetraploid species, *H. rostellatus*, and in African and Indian octoploid species, New World tetraploid and decaploid species, and Australian and Malesian hexaploid species. (Craven & al.

2003; Fernández & al. 2003; Lavia & Fernández 2004; Menzel & al. 1983a; Menzel & Martin 1970, 1980; Wilson 1994). Electrophoretic data suggest that the G genome occurs also in the Hawaiian octoploid, *H. brackenridgei* subsp. *mokuleainus* (Menzel & Hancock 1984). Because of the striking morphological similarity among the American taxa, and among the Australian taxa, it seems likely that chromosome numbers and genome formulae will prove to be the same in the unanalyzed taxa as in the analyzed ones (American: 36, GP; Australian: 54, G_a JV).

The A, X, and Y genomes are restricted to Africa (except for some adventive and cultivated species that originated in Africa) and occur only in diploid and tetraploid taxa (Menzel & al. 1983b; Menzel & Martin 1970; Menzel & Wilson 1961, 1966, 1969). The B genome, represented by the single wide-ranging diploid species in Africa, Asia and Malesia, *H. surattensis*, also occurs in African and Asian tetraploids and octoploids (Menzel & Hancock 1984; Menzel & Martin 1970; Menzel & Wilson 1961, 1966, 1969). The C, D, and E genomes occur in the two subspecies of *H. diversifolius* and in the American decaploid, *H. maculatus* (the latter also carries the apparently unique R genome) (Menzel & Hancock 1984). There is also a possibility that the C, D, E, and G genomes

occur in the Fijian decaploid, *H. fijiensis* (Wilson 1993). The H genome is apparently unique to the African tetraploid, *H. rostellatus* (Menzel & Martin 1970). The J genome, found in the Australian hexaploids, is apparently also present in the Hawaiian octoploid *H. brackenridgei* subsp. *mokuleianus* (Menzel & Hancock 1984). The P genome is apparently unique to the American tetraploid species (Menzel & al. 1983a) and the V genome is apparently unique to the Australian

hexaploid species (Menzel & Martin 1980).

Thus, in *Hibiscus* section *Furcaria*, important mechanisms of speciation have been genome divergence at the diploid level, followed by extensive hybridization and allopolyploidy, significant species radiation at the tetraploid level (the American GP species), and at the hexaploid level (the Australian G_a JV species), and even the emergence of octoploid and decaploid species (Wilson 1994).

Table 2. Chromosome numbers, genomes and geographic distribution of recognized taxa of *Hibiscus* section *Furcaria*, 2006

TAXON	CHROMOSOME NUMBER (n)	GENOME(S)	Geographic Distribution
Africa, Asia and Malesia

¹U = Unknown genome or chromosome number²A purple-flowered form of *H. diversifolius* occurs at Lake Euramoo, Atherton Tableland, N. Queensland, but is not referable to the *H. diversifolius* subsp. *rivularis* of Africa and Brazil.³Provisional genome formulae (Menzel & al. 1986)⁴As *H. meeusei* Exell (Menzel & al. 1986)⁵As *H. heterophyllus* subsp. *luteus* (Hochr.) F. D. Wilson (Menzel & Martin 1974)⁶As *H. spinulosus* (W. V. Fitz.) F. D. Wilson (Menzel & Martin 1974)⁷As *H. laxiflorus* (Menzel & al. 1983a)⁸*H. cerradoensis* Menzel, Fryxell & F. D. Wilson is a synonym of *H. laxiflorus* (Menzel & al. 1983a).⁹As *H. kitaibelifolius* (Menzel & al. 1983a)

Acknowledgments

I thank L. A. Craven (Australian National Herbarium) and P. A. Fryxell (Claremont, CA) for reviews.
